

What it does?

Turns a business requirement into a proper Functional Design Document (FDD) as a .docx:

- Sections,
- Structure,
- Sign-off Table,
- All of it

If you upload your own template, it fills that one (matching its style if it's a blank shell, or filling its placeholders if it has any) instead of using Vaibe's default structure.

It can also suggest which standard SAP tables, CDS views, function modules, BAPIs, or OData services fit your requirement, phrased for a functional reader, flagged for your technical team to confirm.

This is the functional counterpart to **vaibe-sap-developer** agent that writes ABAP/CDS/RAP code to match it's the business-facing design doc. Neither does the other's job.

How to start?

Just ask normally

E.g.:

- "Write an FDD for a vendor invoice auto-block requirement"
- "I need a functional design doc for a new approval workflow in MM"
- "Fill this FDD template" (attach the .docx)"
- "Draft the functional spec for this interface requirement" (then describe it)"

You don't need to name the skill — mentioning FDD, functional spec, business requirement document, or "design document" for an SAP process is enough.

What happens next?

1. **A few tappable-button questions** module/area, requirement type (new / change / enhancement / interface / reporting), system landscape, whether you have a template to upload, and whether you want suggested technical objects included. Labelled "Question 1 of X."

2. **A details form** business background, as-is/to-be process, data elements, integration touchpoints, reporting needs, authorization notes, assumptions, risks, document control (author/owner/approver).

Follow Us On

3. **Fill in what you know:** blanks become a clearly-flagged < TBD — confirm with business > instead of an invented value.

If you said you have a template: you're asked to attach it. Otherwise it proceeds with Vaibe's default 18-section structure.

If you opted in to technical suggestions: a "Suggested Technical Approach" section gets added — standard object recommendations, each one stamped "to be confirmed by technical team."

4. **Output:** You get the first draft .docx as output.

Worth having ready before you start:

To-Be Process Map, Template, Requirements, Names of any specific standard objects you already know should be used — these get folded in alongside, not overridden by, the skill's own suggestions. Anything you don't have yet — skip it. The flow keeps moving with partial answers and flags the gaps instead of guessing.

A few things to know:

Template handling is automatic: if your template has placeholder text/content controls, it gets a strict fill (your formatting and branding untouched). if it's just a styled shell or a past example FDD, the skill matches its look in a freshly generated file instead. Technical suggestions are advisory, not final — they're built from general SAP knowledge of what a given business need typically uses, not from knowledge of your actual system. Every suggested object name is flagged for your technical team to confirm; none is presented as a settled fact about your landscape.

"Not known yet" is a valid answer on any field — it just becomes a visible <TBD> in the doc rather than a guess.

The generated .docx itself carries no Vaibe branding — only the in-chat banner does. It's your client-facing sign-off document. A custom authorization object name, if you're checking against one that isn't standard.

What this skill won't do?

Write or design the actual technical object no ABAP code, CDS syntax, RAP BO definitions, BAPI parameter mapping.

Invent specifics about your particular system (your custom Z-objects, your actual config, your actual customizations) — only what you tell it, otherwise it's flagged.

Guess at out-of-scope items, dependencies, or approvers you haven't stated — these get flagged for business confirmation rather than assumed.
